WATERTOWN ARSENAL LABORATORY

MEMORANDUM REPORT NO. WAL 710/702

A
Twenty-Fourth Partial Report on Problem B-8.2

21 October 1944

Resistance of Variously Heat-Treated Samples of
Ni-Mo and Si-Cr-Mo-Zr Steels to Perforation
by Fragment-Simulating Projectiles

1. At the request of the Office, Chief of Ordnance¹, tests have recently been conducted at this arsenal to determine the resistance of variously heat-treated samples of nickel-molybdenum and silicon-chromium-molybdenum-zirconium steels to perforation by fragment-simulating projectiles.

2. Although the resistance of the as-quenched samples of the silicon-chromium-molybdenum-zirconium steel as well as that of samples of the same composition drawn at 300°F. was considerably better than that of the other samples tested, it did not begin to compare with the resistance provided by an equivalent weight of Hadfield manganese steel under impact of the same types of projectiles.

3. Samples of each composition as heat-treated by seven different methods were clamped rigidly to wooden ballistic frames and impacted in unsupported areas with cal. .45 steel-jacketed ball projectiles and with fragment-simulating projectiles G-1-A, G-1-S² and G-2³, developed at this arsenal. The results are recited in Table I along with hardness and thickness determinations made here.

4. The discrepancy between the ladle carbon and the final carbon content of the Ni-Mo steel indicative of decarburization, is undoubtedly connected with the generally low resistance of samples of this composition as compared with that of samples of the other composition.

5. Apparently little or no correlation exists between the hardness of these samples and their resistance to perforation by the various projectiles used. The

great variance in the hardness of samples of the same composition with identical nominal heat-treatment reflects poor control of the heat-treatment processes.

6. The results of these tests offer further corroboration to the contention that, in the range of weight-per-unit-area currently under consideration for use in body armor, the resistance afforded by Hadfield manganese steel of good quality cannot be equalled by that of any other steel.
